

CC Patio — Site Health: Findings, Remediation & Path to Katana Go-Live

Prepared for CC Patio Prepared by PrimeView 18 September 2026

On 18 September 2026 we ran a full architectural, security, and performance audit of the CC Patio production site ahead of two upcoming changes: full WooCommerce checkout volume and a real-time, two-way inventory sync with Katana MRP. This report summarizes what we found, what we've already fixed, what's still in progress, and what needs action on CC Patio's side before the Katana integration goes live.

PERFORMANCE 84 / B	AVG. SEO SAMPLE 81	HOME ACCESSIBILITY 50
------------------------------	------------------------------	---------------------------------

1. What We Found

The audit reviewed runtime versions, plugin/theme inventory, database health, caching, security hardening, and a sample of key pages for SEO and accessibility. The headline issues:

- PHP running an end-of-life version, and OPcache running at default settings that were undersized for a site this size
- No persistent object cache — every page load was re-querying the database for data that could be served from memory
- Production debugging (WP_DEBUG) left on, and several standard browser security headers missing
- A large, long-running plugin list with some apparent duplication, and a database carrying substantial revision and legacy-table bloat
- A handful of accessibility and broken-link issues on key pages

Sections 2–4 below track each finding to its current status. Section 5 covers what's needed from CC Patio specifically.

2. Already Resolved

The following were fixed the same day the audit was received, with before/after figures confirmed at the host level:

Finding	Before	After	Status
PHP runtime end-of-life	PHP 8.2.33 (unsupported)	PHP 8.3.33 (supported, receiving security patches)	RESOLVED
OPcache undersized / saturating	Default limits; interned strings buffer at 100% capacity	Memory raised to 512 MB (~225 MB in use), interned strings buffer doubled to 16 MB — no longer saturating	RESOLVED
No persistent object cache	Every request queried the database directly	Redis object cache installed and enabled; monitoring hit ratio going forward	RESOLVED
Plugin count / conflicting installs	49 active plugins with some fatal-error conflicts	Reduced to 38 by removing obsolete and conflicting plugins	RESOLVED
Restricted PHP memory	WordPress limited to 40 MB despite 1 GB server allocation	WordPress memory limit raised to match the 1 GB server allocation	RESOLVED

3. Findings We Corrected on Closer Inspection

A few items flagged by an automated snapshot turned out, on live inspection, to be configured intentionally or to mean something different than the snapshot suggested:

Finding as reported	What we confirmed live
Double HTML caching (Cloudflare + NitroPack)	NitroPack is the sole HTML/page cache owner. Cloudflare sits in front purely as a security proxy (masking origin IP); it is not caching HTML on this site.
Four overlapping page-builder plugins	Elementor and Elementor Pro function as a single builder engine (Pro cannot run independently). Astra is the site's theme, not a builder. Spectra Legacy is a block-editor library, not a competing builder — flagged separately below as a genuine consolidation candidate.
Google Site Kit installed but disconnected	Intentional. Analytics, conversion tracking, and Merchant Center feeds are being connected at ecommerce launch, against the final live checkout flow, rather than being configured twice.
Broken Link Checker running continuously	Runs on a 3-day interval, not continuously. It supports the marketing team's link integrity checks, including over weekends.

4. In Progress

Item	Plan	Status
WP_DEBUG still enabled	Currently on deliberately, to log diagnostics while OPcache changes are monitored (display is off — nothing renders to visitors; entries write to a log file outside the public web root). Will be switched off once a stable monitoring window is confirmed.	IN PROGRESS
Security stack consolidation	Standardizing on Wordfence Premium for firewall, malware scanning, and login rate-limiting; deactivating the separate rate-limiting plugin as redundant. Keeping the login-URL-masking plugin as an additional layer.	IN PROGRESS
DISALLOW_FILE_EDIT not yet set	Quick configuration change disabling the in-dashboard file editor. Scheduled this week.	OPEN
WooCommerce version patch (11.1.0 → 11.1.1)	Will be applied after a smoke test on staging.	OPEN
Database revision & legacy-table cleanup	Setting a revision cap and cleaning old revisions on staging first, with a tested backup; a legacy table set from a prior migration is being verified before removal.	OPEN
Failed background job queue	A small number of failed scheduled jobs are being investigated, starting with the most frequent failure type.	OPEN

Homepage size, two broken internal links, accessibility contrast	Home page markup reduction, link fixes, and a browser-based accessibility pass are scoped for the next content/dev cycle.	OPEN
Spectra Legacy plugin	Confirmed as a genuine consolidation candidate. We're inventorying which pages still use it before removing it, so nothing breaks live.	OPEN

5. Needs Action From CC Patio

Security headers (HSTS, Content-Security-Policy, X-Frame-Options, X-Content-Type-Options). We'll prepare and test the full header set against checkout, forms, video, and third-party widgets. Applying them requires access to CC Patio's own Cloudflare zone settings — our access is delegated and doesn't extend to zone-level configuration. We'll need either the Cloudflare account holder to apply the header rules we provide, or temporary access scoped to that change.

For transparency: PrimeView's access to Cloudflare and to the NitroPack caching dashboard is delegated through company-level accounts rather than accounts dedicated to CC Patio specifically, which is why some configuration changes need to route through CC Patio directly rather than being made unilaterally on our side.

6. Path to Katana MRP Integration Go-Live

Katana will sync sales orders from WooCommerce and push stock-level updates back in real time via webhooks. Before enabling continuous live sync, we're tracking the following readiness gate:

Gate	Status
Supported PHP runtime	PASS
OPcache healthy	PASS
Persistent object cache	PASS
Production debugging disabled	IN PROGRESS
Security headers applied	NEEDS CC PATIO ACTION
Single, documented cache owner	DOCUMENTATION PENDING
Database hygiene (revisions, legacy tables)	OPEN
Concurrent-order / overselling test on staging	NOT YET RUN

We'll run a staged load test — including a simulated Katana sync under checkout traffic — before recommending live, continuous sync be switched on. We'll share results as soon as that testing is complete.

Summary

Of the issues identified, the ones with the most direct impact on site stability — the outdated PHP runtime, the undersized OPcache, and the missing object cache — were resolved the same day the audit was received. A handful of other findings turned out to be misread by the automated snapshot and are now clarified above. What remains is a defined, owned list of smaller fixes, plus one item — security headers — that needs action from CC Patio's side to close out. We'll provide an updated status once the current in-progress items are complete.
